 Lund University

1

## Antennas and Propagation for Wireless Systems

One important aspect is **how** the propagation channel and antenna(s) interact.

- The antenna **pattern** determines what the system sees!
- The delay and angular characteristics of the channel are **dependent** on the antenna pattern.

The user equipment (UE) will also naturally have a large influence on the behavior of the antenna, and therefore how it **sees** the channel.

- Change in the UE position will lead to change in the antenna pattern.
- Change in the antenna **pattern** leads to a change in the net **gain** and therefore, a change in the **efficiency** of the antenna!

2

## Examples of Typical Antennas at TX and RX Link Ends

### Antennas and propagation interaction at the RX (UE):

- ❑ Mock-up terminals (handsets, even laptops) with integrated antennas and casing
- ❑ Clearly influenced by the **local** scattering environments:
  - ❑ Mobility of the UE, mobility of the scatterers, surrounding environment (indoor vs. outdoor)

### At the TX side (consider a base station transmitting):

- ❑ Type of installation – elevated on a tower, above the rooftop, or wall mounted.
- ❑ Obstacles or buildings near-by avoided but this gives rise to higher diffraction angles.

Courtesy: Ericsson AB, Sweden

3

## Characterization of Antennas: Key Parameters

- ❑ **Directivity:** Total radiated power in a certain direction relative to the total transmitted power. Note that the gain and the directivity of an antenna are linked to each other.
- ❑ **Efficiency:** The efficiency of an antenna is a ratio of the power delivered to the antenna relative to the power radiated from the antenna.
- ❑ **Q-factor (a.k.a. quality factor):** Energy stored within the antenna compared to energy dissipated out of the antenna.
- ❑ **Mean effective gain:** Include influence of random channel. It is the average received power compared to average received power by isotropic antenna in real environment.

4

## 3D Antenna Radiation Patterns: A 5G Example

### BS: 16x16 cross-polarized UPA: 8(rows)x16(cols.)x2(pol.)

- ❑ Spacing:  $\lambda/2$  in azimuth,  $\lambda$  in elevation
- ❑ Directional gain: 8 dBi (per-element)
- ❑ Half power beamwidth (HPBW): 8° in azimuth and elevation.
- ❑ Slant angle: 45°

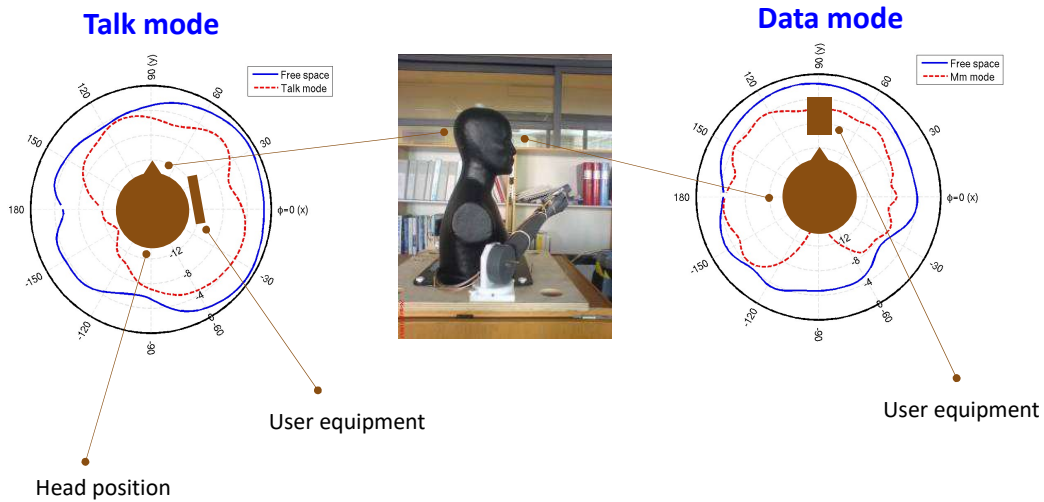

### UE: 4x4 cross-polarized UPA: 2x4x2

- ❑ Spacing:  $\lambda/2$  spacing in azimuth,  $\lambda$  in elevation
- ❑ Directional gain: 9 dBi (per-element)
- ❑ HPBW: 63° in azimuth and 32° in elevation.
- ❑ Slant angle: 45°

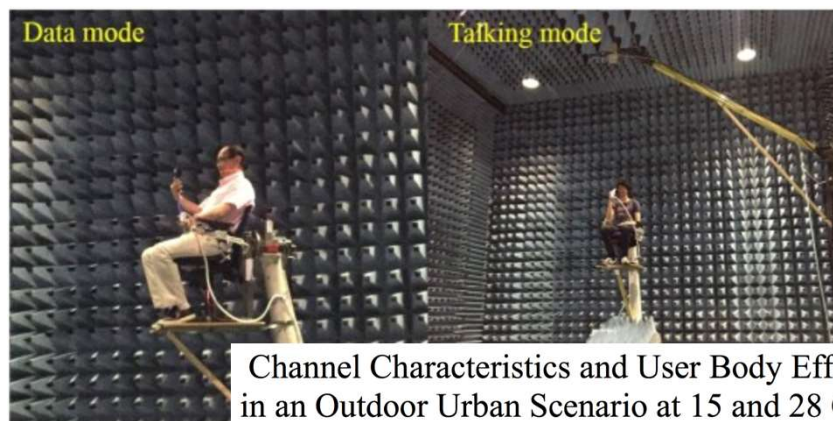

5

## Influence of User Equipment Position and Orientation

6

## Influence of a User: Continuation

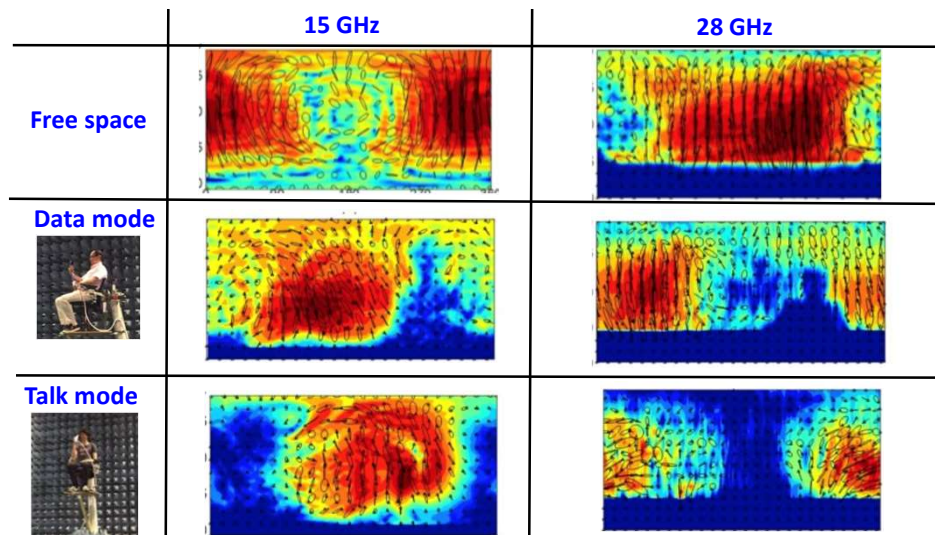

Channel Characteristics and User Body Effects  
in an Outdoor Urban Scenario at 15 and 28 GHz

7

## Influence of a User: Continuation

8

## Some Common Antenna Element Types

- ❑ Linear antennas (monopole, dipole,...)
- ❑ Helical antennas
- ❑ Microstrip antennas (patch elements,...)
- ❑ Planar inverted f antennas...

9

## Linear and Helical Antenna Characterization

### Hertzian dipole (short dipole):

Antenna pattern:  $\tilde{G}(\varphi, \theta) \propto \sin(\theta)$

Uniform across  $\varphi$

### Lambda/2 dipole:

Antenna pattern:  $\tilde{G}(\varphi, \theta) \propto \frac{\cos(\frac{\pi}{2} \cos(\theta))}{\sin(\theta)}$

### Helical antenna: Combination of loop+linear antenna

- ❑ If dimensions much smaller than wavelength, behaviour similar to a linear antenna.
- ❑ Bandwidth, and radiation efficiency increase with increasing  $h$ .

10

## Microstrip Antennas

Dielectric substrate with ground plane on one side, and metallic patch on the other.

**Properties determined by:**

- Shape of the patch
- Dielectric (electrical) properties of the substrate used

Absolute permittivity:  $\epsilon_r$ , a measure of capacitance encountered when forming an electric field in a particular medium. Charge needed for unit flux generation.

**Advantages:**

- Small; can be manufactured cheaply
- Feedlines can be manufactured on same substrate as antenna can be integrated into the UE, without sticking out from the casing.

**Drawbacks:**

- Low bandwidth
- Low efficiency

11

## UE Antenna Types: From 1G to 5G

Monopole

Helix

Patch

12

## Multiple Band Integrated Antennas

For many applications, different wireless services need to be covered

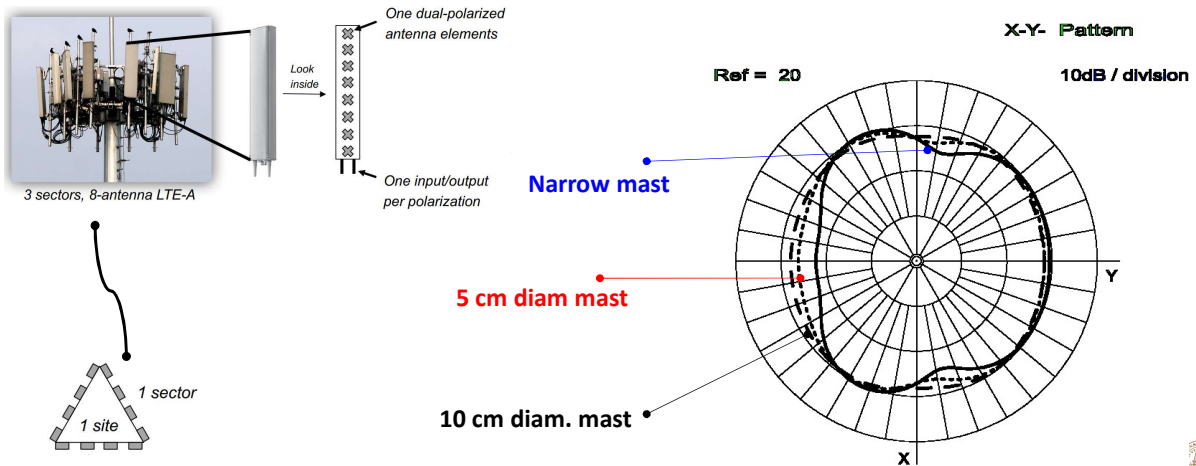

**Example: An old cellular handset needs:**

- ❑ GSM 900 MHz
- ❑ GSM 1800 MHz
- ❑ GSM 1900 MHz, and
- ❑ Bluetooth

13

## Base Station Antennas (a.k.a. Panel Antennas) – I

**Base station antenna pattern affected by the mast (30 cm from antenna)**

14

## Base Station Antennas (a.k.a. Panel Antennas) - II

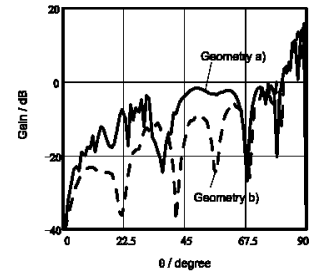

3 sectors, 8-antenna LTE-A

a)

b)

c)

Base station antenna pattern affected by the concrete foundation too!

15

## Multiple Antenna (a.k.a. MIMO) Systems

A "MIMO" system consists of **several** antenna elements, plus **adaptive** signal processing, at both transmitter and receiver, the combination of which exploits the **spatial dimension** of the mobile radio channel.

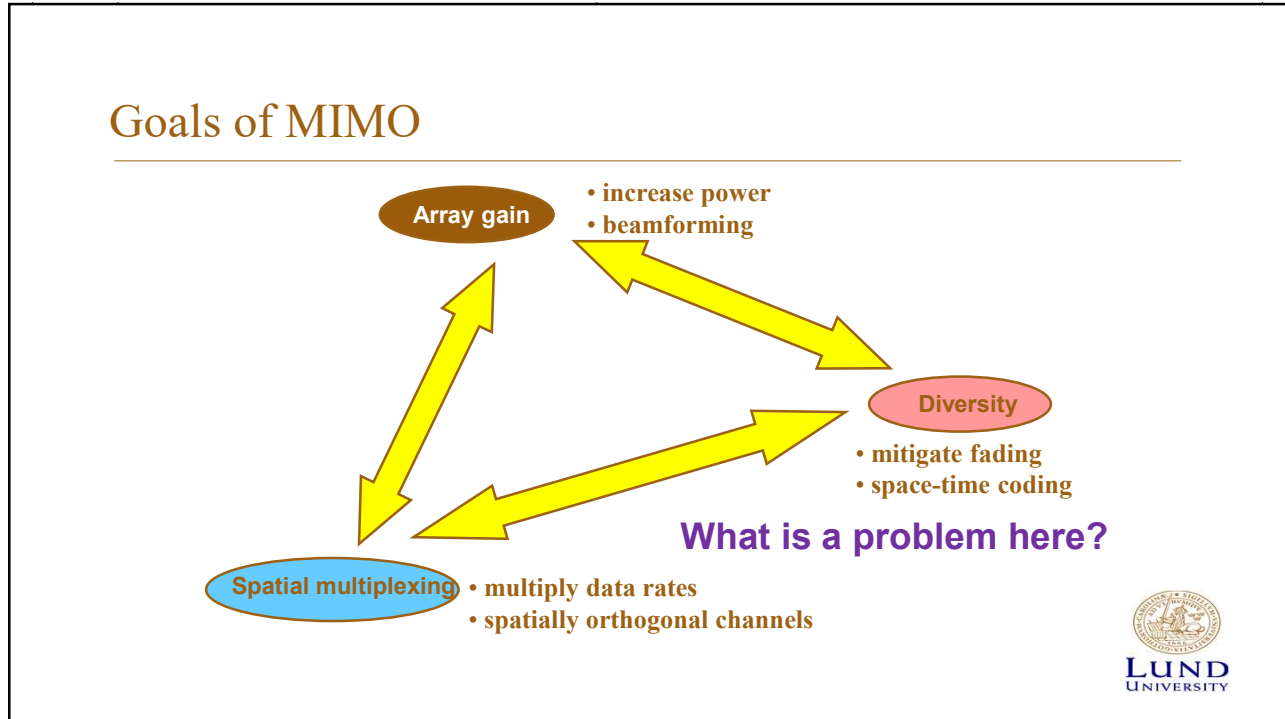

Multiple antennas make transceivers spatially sensitive!

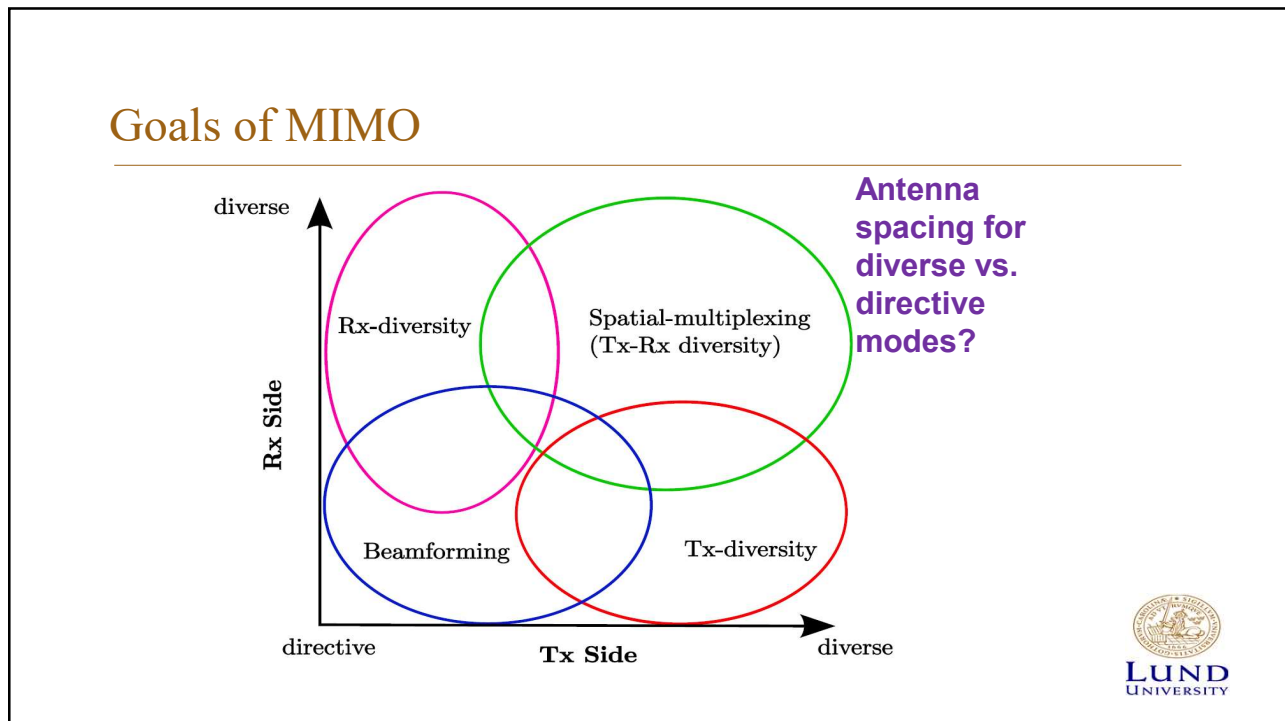

16

17

18

## Benifits of MIMO Systems

- ❑ Higher spectral efficiency and capacity (higher bits/seconds/Hz)
- ❑ Better utilization of spectrum, which is expensive; but number of base stations limited (unless we talk of massive MIMO where we can use hundreds of elements)
- ❑ Better transmission quality
- ❑ Increased coverage due to higher array gain!
  - ❑ Directional antennas have gain and received power:  $P_R = G_T G_R P_T / (N 4\pi d)^2$
  - ❑ UE moves: follow UE with main beam of BS to steer the gain to UE
- ❑ Improved user position estimation

19

## Diversity vs. beamforming

Diversity: statistical independence of elements

Beamforming: coherence between elements

20

## Spatial multiplexing

Each MPC can carry independent data stream

Beamforming view:

- TX antenna “targets” energy onto one scatterer
- RX antenna receives only from that direction

Capacity goes linearly with number of antennas

21

## History

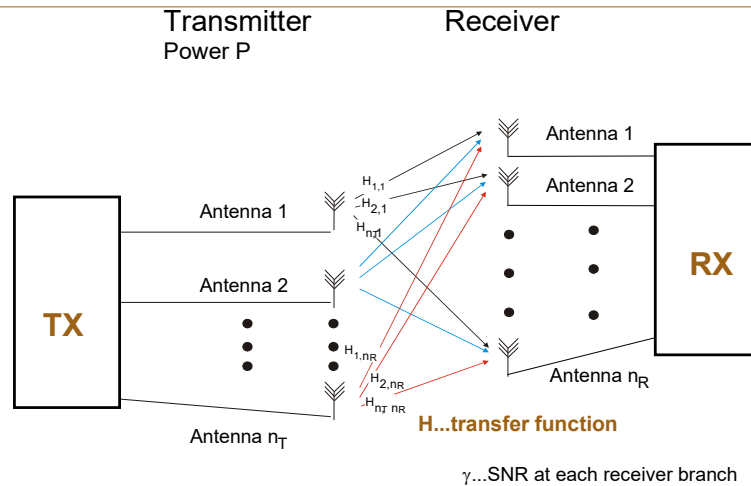

- Diversity:
  - Receive diversity: since 1940s
  - Transmit diversity: early 1990s
    - » Wittneben; Winters
  - Space-time codes in late 1990s
    - » Tarokh et al.; Alamouti
- Spatial multiplexing:
  - Invented by Winters 1987
  - Theoretical treatment in mid-1990s
    - » Winters Foschini&Gans; Telatar; Raleigh and Cioffi

**Examples of wireless systems with MIMO technology?**

22

## Signal model

23

## Narrow-band vs broad-band models

For a narrow-band channel:

$\mathbf{H}$  is an  $n_{R_x} \times n_{T_x}$  matrix.

$\mathbf{y} = \mathbf{H}\mathbf{x} + \mathbf{n}$ , where

$\mathbf{y} = [y_1 \ y_2 \ \dots \ y_{n_{R_x}}]^T$ , ← receive signal vector

$\mathbf{x} = [x_1 \ x_2 \ \dots \ x_{n_{T_x}}]^T$ , ← transmit signal vector

$\mathbf{n}$  is a noise vector where :

$$\mathbb{E} [\mathbf{n}\mathbf{n}^H] = \sigma^2 \mathbb{I}_{n_{R_x} \times n_{R_x}}$$

Ideally,  $\mathbf{H}$  is assumed to be i.i.d. ← Often not true!

Wideband channel matrix entries are frequency dependent

24

## Capacity formula

---

Instantaneous channel characterized by matrix  $\mathbf{H}$

- Shannon's formula (for two-dimensional symbols):

$$C = \log_2(1 + \gamma |H|^2) \text{ bits / s / Hz}$$

- Foschini's formula:

$$C = \log_2 \left( \det \left[ \mathbf{I}_{n_r} + \frac{\gamma}{n_T} \mathbf{H}\mathbf{H}^H \right] \right) \text{ bits / s / Hz}$$

25

## Capacity in realistic channels

---

Influence of various effects:

- Correlation: line-of-sight component, small angular spread
- Frequency selectivity: gives additional diversity
- Limited number of effective scatterers

26

## Channel knowledge is important for the system

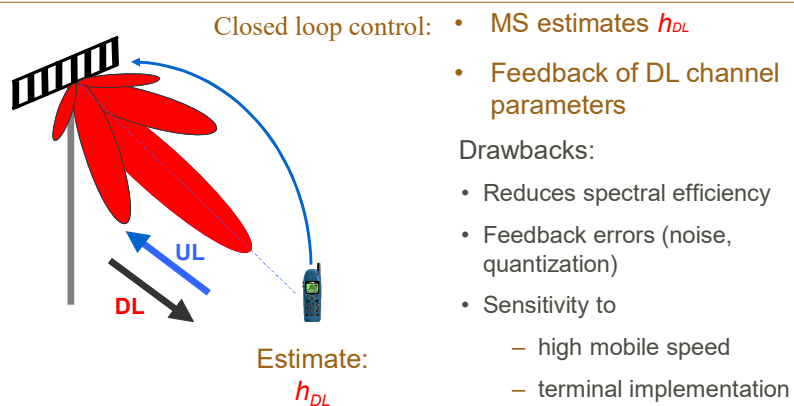

- Channel knowledge at RX
  - unknown
  - known (estimated or perfect)
- Channel knowledge at TX
  - unknown (no channel state information, CSI)
  - average CSI known
  - instantaneous CSI known (estimated or perfect)

Different strategies for different combinations!

27
